## **Chaining Methods 2: Order Matters!**

You have the following functions defined below (read them carefully!):

```
fun is-female(r): r["sex"] == "female" end
fun kilograms(r): r["pounds"] / 2.2 end
fun is-heavy(r): r["kilos"] > 25 end
```

## The table t below represents four animals from the shelter:

name	sex	age	fixed	pounds
"Toggle"	"female"	3	true	48
"Fritz"	"male"	4	true	92
"Nori"	"female"	6	true	35.3
"Maple"	"female"	3	true	51.6

*Match* each Pyret expression (left) to the description of what it does (right). **Note: one description might match multiple expressions!** 

t.order-by("kilos", true)	1	Α	Produces a table containing Toggle, Nori and Maple, with an extra column showing their weight in kilograms
<pre>t.filter(is-female)   .build-column("kilos", kilograms)</pre>	2	В	Produces a table containing Maple, Nori and Toggle (in that order)
<pre>t.build-column("kilos", kilograms)    .filter(is-heavy)</pre>	3	С	Produces a table containing only Fritz, with a single extra column called kilos
<pre>t.filter(is-heavy)   .build-column("kilos", kilograms)</pre>	4	D	Won't run: will produce an error
<pre>t.build-column("kilos", kilograms)   .filter(is-heavy)   .order-by("sex", true)</pre>	5	Ε	Produces a table containing only Fritz, with two extra columns
<pre>t.build-column("female", is-female)   .build-column("kilos", kilograms)   .filter(is-heavy)</pre>	6	F	Produces a table containing Maple and Fritz
